

The Cointegration Relations Between Azerbaijan's GDP and the Balances of the Trade Relations of Russia and Belarus

E.G.Orudzhev, S.M.Huseynova

Abstract. An econometric analysis of the dependence of Azerbaijan's GDP from the balance of the Russian Federation and the balance of Belarus was conducted according to the 26 year's statistical indicators. Relevant statistical methods were applied to check the model's identification and the significance for each parameter and determine the adequacy. The issue of stationarity of the sequences in the work was checked through the Dickey-Fuller Test and the stationarity of the new sequences formed from the second-range difference operators of these time sequences were determined. And then, the mutual cause-result dependencies between these sequences were studied through the Granger Test, the cointegration vectors of these dependencies were determined by applying the Johansen Test, the error correction model was built by studying the error correction mechanisms for the operators built from the differences of the time sequences, and it was demonstrated that the assessments achieved through these models were adequate to the actual data by building cointegration models to get long-term relations ensuring the return of short-term tendencies from the balance position to that position.

Key Words and Phrases: Multiply regression analyses, stationarity, vector error correction, Granger test, determination coefficient, cointegration.

2010 Mathematics Subject Classifications: 91B82, 91G70, 97M10, 97K80

1. Introduction

In the process of long-term joint development within the framework of the united public economy complex of post-Soviet countries, the integration relations of micro and macro indicators between the countries have developed. Under the influence of the united center, relations between the republics have been enhanced and the economic indicators between the countries have been mutually integrated into each other.

The international economic integration under the modern conditions is a rational, normal result of the transnationalization of macroeconomic processes. Comprehensive studies of the global economy's tendencies and Azerbaijan's trade relations, making of justified forecasts by considering regional characteristics and the geographical positions

of countries plays a significant role in the determination of the development strategy of foreign trade.

The major part of importation and exportation transactions of Azerbaijan with the post-Soviet countries falls to Russian Federation' share. The Republics of Kazakhstan, Belarus and Ukraine rank in the second and third places respectively [1]. The direction of economic relations of the post-Soviet states from the near abroad to far foreign countries under the conditions of increasing dependence from the global market have led to significant structural changes in the structure of the import-export transactions and the manufacturing sphere in the CIS countries.

The current key tendencies in the global economy are the integration of national economies, international globalization, and increasing of labor resources and free capital between countries. The influence of this process may lead to both positive and negative results. In order to draft an economic policy with the nature of foreign integration, the dynamics of macroeconomic development indicators of the national economies of the abovementioned countries should be analyzed, the economic growth safety should be assessed potentially, and the long-term trends of the integration process should be described in comparison to statistic data. In order to achieve an effective integration, forecasting by building and analyzing of the co-integration relations between the GDPs and other inclusive economic growth parameters of these countries is a very hot topic.

It is one of the key issues set to improve the social-economic spheres in the post-Soviet countries through new innovative methods in the studies of the projects implemented in the priority directions in the spheres ensuring the sustainable economic development of the countries in the future.

2. Analyses of the recent research and publications.

According to this principle, the processes of increasing the investments in human resources, reducing the percentage indicator of poverty, developing the entrepreneurship, the social economic development of regions in addition to urban places, the restoration of the economic balance between regions, the elimination of the difference observed in the social lives of the regions, the employment of population, and the key directions of the growth of country economy for future years in the post-Soviet countries are analyzed for certain economic spheres in [2]. Also, in [1-6], the inclusive parameters and their role in the country economy are individually analyzed, and the reflection of the inclusive economic development within the development of the social-economic spheres of the country is specified. Adequate analyses show that investments in human resources, the development of infrastructure, the economic development through innovative methods, and the inclusive development of social spheres increase the tempo of the economic sustainable development in the country. For the future economic development of the countries, firstly, prioritization of the development of inclusive parameters in the country, the use of both social and economic efficiencies of the regions and the balancing of their development, the development of integration relations between the countries, including the increasing of the trade turnover between the countries, and the increasing of the quality of social services

in the country may be assessed as the result of the analyses conducted in [6].

The development of inclusive economic parameters, including foreign economic relations is the key condition for the acceleration of the integration of national economies of various countries at the international economic range. In order to meet this condition, countries should join economic integration flows, thus, try to increase their manufacturing capacities, manufacturing efficiencies and ultimately, the common wealth level of their populations. The inclusive economic development between the post-Soviet countries from this point of view may be accepted as the key factor in ensuring of the sustainable economic development between the countries.

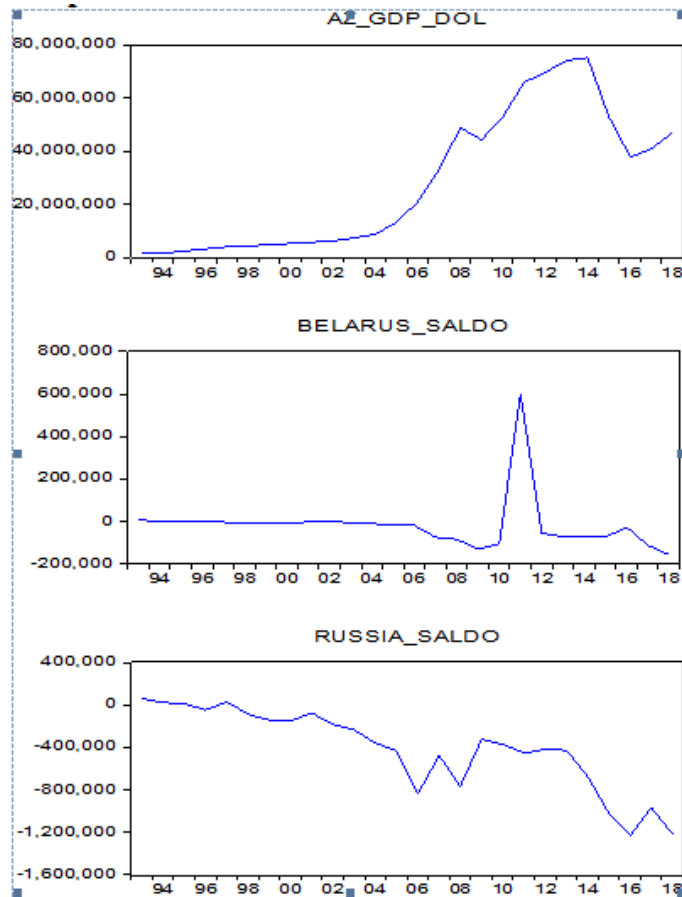

It is possible to achieve economic development between the post-Soviet countries and make a substantial turn in the inclusive economic development between the countries by maximally using the advantages of the international labor distribution and intensively enhancing all forms of foreign economic relations. In order to realize this turn, these countries try to build bilateral and regional economic relations.

For the case that we study, we should mention that the relations between Russia, Belarus and the Republic of Azerbaijan in various spheres of economy, including energetics, agriculture, trade, pharmacy, tourism and etc. are developing and there are potential capacities to enhance the cooperation.

3. Purpose of research

Taking into consideration the abovementioned, an econometric study of the dependence of Azerbaijan's GDP from certain elements of the economic inclusive parameters of the Russian Federation and the Republic of Belarus in the time period from 1993 to 2018 is conducted. According to statistical indicators, the dependence of Azerbaijan's GDP from the balance of the trade relations between Russia and Belarus is econometrically analyzed.

Time period from 1993 to 2018, dynamic description of the relationship between dependent and explanatory variables is as follows:

Graph 1:

Recommendations justified with econometric approaches are provided by using the procedures of the Eviews software package, realizing co-integration relations, analyzing the economic interpretations of results in order to give long-term forecasts.

| Prob(F-statistic) | 0.003176 | | | |

The linear multi-factor regression equality describing the dependency of Azerbaijan's GDP in thousands of USD (AZ_GDP_DOL) from the indicators of thousands of USD balances of Russian Federation (RUSSIA_SALDO) and Belarus (BELARUS_SALDO) will be as follows formally.

$$AZ_GDP_DOL = 29.6002446013 * BELARUS_SALDO - 43.1759404878 * RUSSIA_SALDO + 10733601.0684$$

The description of the relationship between dependent and explanatory variables is as follows:

Graph 2.

The statistical information here were taken from the official electronic sources of the State Statistics Committee of Azerbaijan [7].

The value of indicator of the determination coefficient in the table demonstrates that the variation of the independent variables provided in the model explains 39% of the variation of the dependent AZ_GDP_DOL. The density of relation is very low in this case.

Let's see the F-Fisher Test to check the significance of the built model. The significant status of the model is accepted true for the case where the result calculated through the F-Fisher Test is higher than the relevant critical value of the F-Fisher statistics, that is, $F_{calculated} > F_{table}$. In order to determine the critical table value of the F-Fisher Test, the significance level (by probability or percentage) and the independence degrees should be determined. Let's see the model in the 5% significance degree in order to check its significance. And we will determine the Test's independence degrees as $k_1 = m - 1$, $k_2 = n - m$ under the given conditions, that is, according to the number of the periods and observations [8, p.79], as it gets the values of $k_1=3-1=2$; $k_2=26-3=23$. The F-Fisher table value will be 3.42 according to the indicators we achieved. Thus, the inequality $F_{calculated} > 3.42$ is met for the model to be significant.

In order to check the significance of the built model through the t-Student criterion, the inequality $|t_{calculated}| > t_{table}$ is checked. Here, the value t_{table} is determined on the basis of the independence degree $d_f = n-2$, as it will be $n=26$, $d_f = 26-2=24$. According to this indicator, the table degree in the 5% significance degree of the t-Student statistics will be $t_{table} = 2.06$. In order the model to be accepted as a significant one for each parameter individually, the inequality $|t_{calculated}| > 2.06$ should be met.

In order to check the existence of auto correlation, the zero hypothesis should be built firstly. The H_0 hypothesis about the absence of auto correlation is determined according to the table value of the Durbin-Watson statistics. $d_L = 1,16$ and $d_U = 1.65$ are found according to the total number of observations $n=23$ and the variable number $k=3$. In

order to check the auto correlation through the built model, the value of the d-statistics was calculated and was $d=0.44$. $d < d_L, d_U$ has been met for this value, the presence of positive auto correlation.

And now, let's see the issue of presence of heteroscedasticity in the model. The heteroscedasticity will lead to the ineffectiveness of the found assessment, as the assessment will not be effective, although it will be coherent. We should mention that in case of presence of heteroscedasticity, the values of standard errors found through the least squares method (LSM) decrease, which result in the decrease in the value of t-statistics and may result in inaccurate study about the significance of the assessment. The heteroscedasticity may also occur due to the inaccurate selection of a model and observation values. In case of presence of heteroscedasticity, the Summarized Least Squares Method (SLSM) is applied [8] .

The model's heteroscedasticity was checked through the White Test in the studied model according to the observation results and the following results were achieved:

Table 2.

| Heteroskedasticity | | | | |
|--------------------------------|-------------|-----------------------|-------------|--------|

| F-statistic | 1.752021 | Durbin-Watson stat | 0.919017 | |
| Prob(F-statistic) | 0.168857 | | | |

And let's now see the issue of stationarity of the studied time sequences. Generally, the stationarity of the reviewed time sequence is very important in terms of econometric analysis. Although the results and the model's quality characteristics achieved when a sequence is not stationary explain the adequacy of the model, they are observed with errors and the built model lose its significance and become invalid for forecasting assessments. Therefore, in order to achieve a significant model from the model we built, the model's stationarity was checked on the basis of the Augmented Dickey-Fuller Test and appropriate results were achieved. In order to check the stationarity in the time sequences formed in the model from the variables, the tools of the united roots methods of the Eviews software package are used.

Table 3. Result of Dickey-Fuller Test

Firstly, it should be checked whether the time sequence formed from the GDP is stationary in comparison to the Dickey-Fuller tests. According to the test results, the new sequence formed with the 2nd range differences has been regarded stationary. We perform the hypothesis $H_0: \alpha_1 = 1$ and the alternative $H_1: \alpha_1 < 1$ hypothesis on 26 observation and 1%, 5% and 10% significance level. The result of test (AR) at $t = -4.904012$, $p = 0.0038$. The obtained level of probability allows rejecting H_0 hypothesis. And also the t-student statistics are less than the critical value of t (at the significance level of 1%, 5% and 10%). The result of the estimation reject H_0 hypothesis and confirm the stationarity of the time series AZ_GDP_DOL. The achieved results are described in the following table.

The interpretation of the Eviews results shows that although the sequence is not stationary, its 2nd differences are stationary.

The Granger Test was used to determine the relationships of the reason and the result in the model. Based on the significant influence of the use of lags formed from causing factors for the dependent variable AZ_GDP_DOL on the results of this test, the lags from 1 to 4 were used. The following table results were achieved by realizing the mechanism in the Eviews software package.

Table 7.

And now, let's test the co-integration relation between the variables. For this, the variables must be stationary. The co-integration relation of the Eviews software package with the Johansen co-integration test is studied. The co-integration test is tested through 2 statistics. One of them is the trace statistics and the Maximum Eigenvalue statistics. The difference of the co-integration test from other tests is that there are sub hypotheses under the hypothesis H_0 , which is due to the testing of the co-integration test. According to the inequalities system. The test results are presented in the following table:

The results are described in the following table: Thus, 5 cases are described in Table 7: $H_2(r)$, $H_1^*(r)$, $H_1(r)$, $H^*(r)$, $H(r)$. $H_2(r)$: there is not a deterministic trend in the data. The co-integration equality does not include the intercept and the trend; $H_1^*(r)$: there is not a deterministic trend in the data. While the co-integration equality includes the intercept, it does not include the trend; $H_1(r)$: there is a deterministic linear trend in the data. While the co-integration equality includes the intercept, it does not include the trend; $H^*(r)$: there is a deterministic linear trend in the data. The co-integration equality includes the intercept and the trend; $H(r)$: there is a deterministic quadratic trend in the data. The co-integration equality includes the intercept and the trend; The co-integration range is assessed as $r=1$ in the first four cases and $r=2$ for case 5. Let's see the case of $H^*(1)$. Information criterion Akaike AIC=85.41299, and information criterion Schwarz=87.25510.

So, if we review the hypothesis $H_0 : r = 0$, we can see that the Max-Eigen Statistic statistics (106.9153) in this hypothesis are higher than the critical value (25.82321). At the same time, the probability value is less than 5%, which allows us to refuse the hypothesis $H_0 : r = 0$. In the hypothesis $H_0 : r = 1$ and $H_0 : r = 2$, the Max-Eigen Statistic are less than the critical value. These cases are not denied. Thus, the assessed co-integration range is equal to 1.

And now, let's see the error correction model by using the tools of the Eviews software package.

The co-integration relations between Azerbaijan's GDP and the balances of the trade relations of Russia and Belarus.

$$D(DGDPAZZ) = - 0.0949844598249*(DGDPAZZ(-1) - 187.03647441*DBELARUSS(-1)+ 39.4837469771*DRUSSIAA(-1) - 1258605.89454) - 0.602554118538*D(DGDPAZZ(-1)) - 1.3878246215*D(DGDPAZZ(-2)) - 1.59672870986*D(DGDPAZZ(-3)) - 42.9482790097*D(DBELARUSS(-1)) - 22.4092719822*D(DBELARUSS(-2)) + 5.21100047516*D(DBELARUSS(-3)) + 7.16487381453*D(DRUSSIAA(-1)) - 6.2567416052*D(DRUSSIAA(-2)) + 0.936419245415*D(DRUSSIAA(-3)) - 967907.658506$$

As a result of the realization of the Granger Test, we stated above that there are contra-relations between the relevant indicators. The following co-integration relations of these dependencies are achieved by conducting the analogical procedures for the indicators of the Belarus-Azerbaijan balance and the Russian-Azerbaijan balance, the Azerbaijani GDP and the Russian-Azerbaijan balance, and the Belarus-Azerbaijan balance and the Azerbaijani GDP in the Eviews software package.

$$D(DBELARUSS) = 0.0266976823284*(DGDPAZZ(-1) - 187.03647441*DBELARUSS(-1) + 39.4837469771*DRUSSIAA(-1) - 1258605.89454) - 0.017007108325*D(DGDPAZZ(-1)) - 0.0401542380502*D(DGDPAZZ(-2))- 0.0390922581296*D(DGDPAZZ(-3)) + 2.34787719424*D(DBELARUSS(-1)) + 1.59038730257*D(DBELARUSS(-2))+ 0.842478271487*D(DBELARUSS(-$$

4. Result.

The results in Table 10 given with Lag dependencies show that the co-integration relation built may be regarded significant for the second-range difference operators formed from the tested time sequences. Thus, the error correction model built allows to assess the quality characteristics of the short-time and long-time dynamics of the relations between the time sequences of the studied indicators, as the assessment of the parameters of the co-integration relation and the determination of the speeds of accrual to the balance position are ensured here. The speeds of the processes of the return of the tendencies from the balance position in the previous time moments with 3 lags to the balance trajectory consecutively in the subsequent moments were determined through the multiplication of relevant invariables. These ratios show how many percentages the tendencies from the balance position have been corrected currently. If the values of these ratios are negative, the remaining tendencies are adequately corrected with percentage statements in the subsequent periods. In order to ensure the dynamic sustainability of the built model, the location of these ratios in the part $[-1,0]$ may be accepted as a necessary precondition. The achieved co-integration relation allows to adequately assess the mutual relation between the studied indicators in comparison to the time moments.

These assessments achieved second difference co integration through correction mechanisms may be accepted as a significant tool in the governmental regulation of the importation and exportation transactions by also considering other influencing factors, providing dynamical analyzes in the conduction of balanced importation-exportation transactions between them in the acceleration of the mutual trade and economic integration of all of these three countries in order to ensure the long-term sustainable growth of the relevant inclusive parameters.

Research shows that without heteroskedasticity and autocorrelation unable to get correct results. Of course, it would be worth considering move from indicators to relative growth rates, and these are the research procedures above for indicators. Just like the trend in the regression model exponential transformation must be implemented. All these cases are systematic comparisons. The analysis is taken into account in future researches of the authors.
